

1      Claims

2      What is claimed is:

3      1. A method for compressing large number of location data of moving objects during a  
4      continuous time, comprising the steps of:

- 5            a) receiving current location data of a moving object;  
6            b) determining whether the object was in motion of translation previously;  
7            c) if determined in step b) the object was in translational motion, determining  
8            whether the object continues to move translationally after taking account of the  
9            current location, if yes, not updating the location data;  
10           d) if determined in step c) the translational motion is no longer observed after  
11           taking account of the current location, updating the location data and returning to  
12           step a); and  
13           e) if determined in step b) the object was not in translational motion, determining  
14           whether the object is moving randomly nearby, if yes, not updating the location  
15           data, otherwise updating the location data, setting the object in motion of  
16           translation and returning to step a).

17           2. The method according to claim 1, wherein the step of updating the location data  
18           includes selecting a location queue with variable length, storing the compressed location  
19           data of the moving object into the variable location queue, then from said location queue,  
20           inserting the location data of the moving object at different time into a database at an  
21           acceptable data insertion rate of the database.

22           3. The method according to claim 2, wherein the topology and physical structure  
23           and location data of roads are stored in advance, and the corrected location data of the  
24           moving object is obtained by a spatial index before step b).

1           4. The method according to claim 3, wherein step c) further comprises the  
2 sub-steps of:

3           c1) using several previous locations of the object to perform linear prediction to the  
4 current location of the object;

5           c2) computing a prediction error between the predicted current location and the  
6 received current location; and

7           c3) if the prediction error is within the range of a linear prediction threshold,  
8 confirming that the moving object continues to move translationally.

9           5. The method according to claim 4, wherein said linear prediction is a first order  
10 polynomial linear prediction of double points or a first order polynomial linear prediction  
11 of multiple points.

12           6. The method according to claim 2, wherein in the case of without stored topology  
13 and physical structure and location data of roads in advance, the step c) further comprises  
14 the sub-steps of:

15           c11) obtaining the time-location linear equation through fitting of the current  
16 location and previous locations where the object was in translational motion;

17           c12) substituting the current time point value and the previous time point values  
18 when translational motion was satisfied into the time-location linear fitting equation and  
19 estimating a fitting error at each time point; and

20           c13) if the fitting errors at all the time points are within the range of linear  
21 prediction threshold, confirming that the moving object continues to move translationally  
22 and setting the fitting location of the object at each time point as the corrected location.

23           7. The method according to claim 5, wherein the step d) further comprises the  
24 sub-steps of:

25           d1) if determined in step c) the translational motion is no longer observed after  
26 taking account of the current location, determining whether the object is moving

1 randomly nearby, if yes, updating the location data and setting the object to be in a state  
2 of moving randomly nearby;

3 d2) if determined in step d1) the object is not in the state of moving randomly  
4 nearby, determining whether the prediction error or fitting error is larger than a specific  
5 error threshold of the object set according to a location query precision, if the prediction  
6 error or fitting error is larger than the specific error threshold of the object set according  
7 to location query precision, determining whether the last recorded location data on the  
8 database and the last corrected location data are identical, if yes, recording the current  
9 location data, otherwise recording the last corrected location data and the current location  
10 data;

11 d3) if the prediction error or fitting error is not larger than the specific error  
12 threshold of the object set according to the location query precision, determining whether  
13 the number of the points satisfying the linear prediction are larger than a threshold, if no,  
14 recording the current location data, and if yes, recording the last corrected location data  
15 and the current location data; and

16 d4) only retaining the current location data in a temporary storage space for  
17 locations satisfying the linear prediction.

18 8. The method according to claim 1, wherein step e) further comprises the  
19 sub-steps of:

20 e1) determining whether the last recorded location data is equal to the last corrected  
21 location data, if no, setting a translational motion flag and recording the current location  
22 data;

23 e2) if determined in step e1) the last recorded location data is equal to the last  
24 corrected location data, determining whether the location prediction error is larger than  
25 the specific threshold set according to the location query precision, if no, only recording  
26 the current location data;

27 e3) if determined in step e2) the location prediction error is larger than the specific  
28 threshold set according to the location query precision, determining whether the number

1 of points satisfying moving randomly nearby threshold are larger than a threshold, if yes,  
2 recording the last corrected location data and the current location data, otherwise only  
3 recording the current location data; and

4 e4) resetting the number of points satisfying moving randomly nearby threshold to  
5 zero, clearing up the data of the previous location, and retaining the last corrected  
6 location data and the current location data in the temporary storage space for the locations  
7 satisfying linear prediction according to the translational motion flag.

8 9. The method according to claim 1, wherein said location queue resides in  
9 memories or exists in form of one or more files.

10 10. The method according of claim 1, wherein an initialization step is performed  
11 before the step a): receiving and recording the first several location data of the moving  
12 object, and determining whether the object is in motion of translation or a state of moving  
13 randomly nearby according to the received first several location data.

14 11. An apparatus for compressing location data of moving objects, comprising:  
15 input interface for receiving current location data of a object moving continuously;  
16 data compression means for compressing the location data received via said input  
17 interface; and

18 output interface for outputting compressed location data of the moving object,  
19 wherein said data compressing means comprises:

20 linear model processing unit for determining, when the moving object was in  
21 motion of translation previously, whether the moving object continues to move  
22 translationally after taking account of the current location, if yes, not updating the  
23 location data, and if no, updating the location data; and

24 simple threshold model processing unit for determining, when the moving object is  
25 not moving translationally, whether the object is moving randomly nearby, if yes, not  
26 updating the location data, otherwise updating the location data.

1           12. The apparatus according to claim 11, further comprises storage means for  
2 storing the topology and physical structure, location data and the temporary results  
3 necessary for data compression.

4           13. The apparatus according to claim 12, wherein said linear model processing unit  
5 comprises:

6           linear prediction means for predicting the current location of the object with several  
7 previous locations of the object;

8           prediction error computing means for computing a prediction error between the  
9 predicted location and the current location; and

10          determination means for confirming the moving object continues to move  
11 translationally if the prediction error is within the range of linear prediction threshold.

12          14. The apparatus according to claim 13, wherein said linear prediction is a first  
13 order polynomial linear prediction of double points or a first order polynomial linear  
14 prediction of multiple points.

15          15. The apparatus according to claim 11, wherein said linear model processing unit  
16 comprises:

17          fitting means for performing the regression between time and locations including  
18 the current location and the previous locations satisfying translational motion to obtain a  
19 fitting time-location linear equation;

20          fitting error estimation means for substituting the current time value and the  
21 previous time values in which translational motion was satisfied into the fitting  
22 time-location linear equation and estimating a fitting error at each time point; and

23          determining means for confirming that the moving object continues to move  
24 translationally if the fitting errors at all the time points are within the range of linear  
25 prediction threshold.

1           16. The apparatus according to claims 11, wherein said output interface comprising  
2 a variable-length location queue which saves the compressed location data of the moving  
3 object to be inserted into a database and inserts the compressed location data of the  
4 moving object at different time into the database at an acceptable data inserting rate of the  
5 database.

6           17. The apparatus according to claim 11, wherein said location queue resides in  
7 memories or exists in form of one or more files.

8           18. An article of manufacture comprising a computer usable medium having  
9 computer readable program code means embodied therein for causing compression of a  
10 large number of location data of moving objects during a continuous time, the computer  
11 readable program code means in said article of manufacture comprising computer  
12 readable program code means for causing a computer to effect the steps of claim 1.

13           19. A program storage device readable by machine, tangibly embodying a program  
14 of instructions executable by the machine to perform method steps for compressing large  
15 number of location data of moving objects during a continuous time, said method steps  
16 comprising the steps of claim 1.

17           20. A computer program product comprising a computer usable medium having  
18 computer readable program code means embodied therein for causing compression of  
19 location data of moving objects, the computer readable program code means in said  
20 computer program product comprising computer readable program code means for  
21 causing a computer to effect the functions of claim 11.
